

SPACINGS AND PAIR CORRELATIONS FOR FINITE BERNOULLI CONVOLUTIONS

ITAI BENJAMINI AND BORIS SOLOMYAK

ABSTRACT. We consider finite Bernoulli convolutions with a parameter $1/2 < \lambda < 1$ supported on a discrete point set, generically of size 2^N . These sequences are uniformly distributed with respect to the infinite Bernoulli convolution measure ν_λ , as $N \rightarrow \infty$. Numerical evidence suggests that for a generic λ , the distribution of spacings between appropriately rescaled points is Poissonian. We obtain some partial results in this direction; for instance, we show that, on average, the pair correlations do not exhibit attraction or repulsion in the limit. On the other hand, for certain algebraic λ the behavior is totally different.

1. INTRODUCTION

With original motivation coming from physics [1], many authors investigated spacings and other statistical properties of various number-theoretic sequences, see e.g. [9, 16, 17, 18] and references therein. Given a sequence $\{\theta_n\}$ equidistributed in the unit interval, the nearest-neighbor spacing distribution is obtained by ordering the first elements of the sequence $\theta_{1,N} \leq \theta_{2,N} \leq \dots \leq \theta_{N,N}$, and then defining normalized spacings to be

$$\delta_n^{(N)} := N(\theta_{n+1,N} - \theta_{n,N}).$$

One can also consider next-to-nearest neighbor spacings or more generally, for any fixed $\ell \geq 1$,

$$\delta_{\ell,n}^{(N)} := N(\theta_{n+\ell,N} - \theta_{n,N}).$$

A function $P_\ell(s)$ is called the limiting distribution function of $\{\delta_{\ell,n}^{(N)}\}$ as $N \rightarrow \infty$ if, for any interval $[a, b] \subset [0, 1)$,

$$(1.1) \quad \lim_{N \rightarrow \infty} \frac{1}{N} \# \{n \leq N : \delta_{\ell,n}^{(N)} \in [a, b]\} = \int_a^b P_\ell(s) ds.$$

Key words and phrases. spacings, Bernoulli convolutions

Research of Solomyak was partially supported by NSF grant #DMS-0654408.

If the points θ_n are independent uniformly distributed on $[0, 1]$ random variables, we get the Poisson model, with

$$P_\ell(s) = \frac{s^{\ell-1}}{(\ell-1)!} e^{-s}, \quad \text{for all } \ell \geq 1.$$

Other widely used statistical measures are correlation functions. The pair correlation function for the sequence $\{\theta_n\}$ is defined by

$$R_2(s, \{\theta_n\}, N) = \frac{1}{N} \# \left\{ (n, m) : n \neq m, n, m \leq N, |\theta_{n,N} - \theta_{m,N}| \leq s \right\}.$$

In the Poisson model we have $R_2(s, \{\theta_n\}, N) \rightarrow 2s$, as $N \rightarrow \infty$.

In this paper, we initiate a study of a similar problem for sequences arising from overlapping iterated function systems and non-standard digit expansions. For $\lambda \in (\frac{1}{2}, 1)$ let

$$A_N(\lambda) = \left\{ (1 - \lambda) \sum_{n=0}^{N-1} a_n \lambda^n : a_n \in \{0, 1\} \right\}.$$

We are interested in the randomness properties of these sets as $N \rightarrow \infty$. Note that a point in $A_N(\lambda)$ may have more than one representation; in other words, we may have “coincidences.” This will happen whenever λ is a zero of a polynomial with coefficients $\{-1, 0, 1\}$, which we call $\{0, \pm 1\}$ polynomials for short. In this case we take the point “with multiplicity,” so that our sequence always has size 2^N . Consider the uniform measure ν_λ^N on $A_N(\lambda)$; this is a discrete measure, with a point in $A_N(\lambda)$ having mass 2^{-N} times the number of representations. It is well-known that for all λ , the measures ν_λ^N converge vaguely to the infinite Bernoulli convolution measure ν_λ , defined as the distribution of the random series $\sum_{n=0}^{\infty} \omega_n (1 - \lambda) \lambda^n$, where ω_n are i.i.d. Bernoulli random variables taking the values 0, 1 with equal probability. Often ± 1 are used as digits instead of 0, 1; this is just a linear change of variable. We also multiplied by $(1 - \lambda)$, so that the measures are all supported on $[0, 1]$. Note that $(\frac{1}{2}, 1)$ is the interesting parameter range for this problem: for $\lambda < 1/2$ the measure ν_λ is supported on a Cantor set, and $A_N(1/2)$ is just the set of binary rationals in $[0, 1)$ with denominators less than 2^N ; also, for $\lambda \leq 1/2$ the ordering of $A_N(\lambda)$ agrees with the lexicographical ordering on $\{0, 1\}^N$.

The measures ν_λ , for $\lambda \in (\frac{1}{2}, 1)$, have been much studied, but are still rather mysterious, with many unsolved problems, see [12] and references therein. Besides mathematics, they come up in physics, information theory, and economics, see e.g. [7, 2, 10]. Briefly, it is known that ν_λ is continuous for all λ , it is either purely absolutely continuous or purely singular, it is absolutely continuous for a.e. $\lambda \in (\frac{1}{2}, 1)$, and it is singular for Pisot reciprocals (see the definition below). It is an open problem whether these are the only exceptions.

The only explicitly known λ for which ν_λ is absolutely continuous are Garsia reciprocals (see the definition below), which include $2^{-1/k}$, for $k \geq 2$. Moreover, the roots of $1/2$ are the only parameters for which the density is explicitly computable. (When we talk about “density of ν_λ ” in this paper, we mean the Radon-Nikodym derivative $\frac{d\nu_\lambda}{dx}$.)

Let $\{\xi_{j,N}\}_{j=1}^{2^N}$ be the ordering of $A_N(\lambda)$, counting with multiplicity, so that

$$0 = \xi_{1,N} \leq \xi_{2,N} \leq \cdots \leq \xi_{2^N,N} = 1 - \lambda^N.$$

Spacing statistics provide a measure of randomness for the sequences $\{\xi_{n,N}\}$ approximating ν_λ . Numerical evidence seems to indicate that, for a typical λ , there exist level spacing distributions. However, we first need to rescale the sequence. Let

$$\tilde{\xi}_{n,N} = F_\lambda(\xi_{n,N}), \quad n = 1, \dots, 2^N, \quad \text{where } F_\lambda(\xi) = \nu_\lambda(-\infty, \xi).$$

These sequences are uniformly distributed modulo one, in the sense that for any interval $[a, b] \subset [0, 1]$, the number of points $\tilde{\xi}_{n,N}$ in $[a, b]$ divided by 2^N tends to $b - a$. (This follows from the fact that ν_λ is continuous, hence the cumulative distribution function (CDF) of ν_λ^N converges to the CDF of ν_λ everywhere.)

Conjecture 1. *For almost every $\lambda \in (\frac{1}{2}, 1)$ the rescaled sequences $\tilde{\xi}_{n,N}$ are distributed according to the Poisson model.*

We have numerical evidence in support of this conjecture, however, proving it seems far beyond our reach. A key difficulty is that very few measures ν_λ are known explicitly. Therefore, we mostly focus on the pair correlation function for the non-rescaled sequences

$$R_2(s, \lambda, 2^N) := \frac{1}{2^N} \# \left\{ (x, y) : x \neq y, x, y \in A_N(\lambda), |x - y| \leq \frac{s}{2^N} \right\}$$

which provide information about the variance of average spacings. A more modest goal than proving Conjecture 1 would be to verify the following

Conjecture 2. *For almost every $\lambda \in (\frac{1}{2}, 1)$, there exist $c, C > 0$ such that*

$$cs \leq R_2(s, \lambda, 2^N) \leq Cs \quad \text{for all } N \text{ and } s > 0.$$

This would mean that our sequences exhibit **no attraction** and **no repulsion**. Our main results (Theorems 2.1 and 2.3) makes a step in this direction, but we have to do averaging over the parameter λ .

Note that for certain λ the behavior of the spacings is definitely not Poissonian. For example, let $\lambda = 1/\theta$, where θ is a Pisot number, that is, an algebraic integer > 1 whose conjugates are all less than one in modulus. Such ν_λ , with $\lambda \in (\frac{1}{2}, 1)$, are the only singular infinite Bernoulli convolutions known [3]. In this case, Garsia's Lemma [6] says that the spacings between distinct points in $A_N(\lambda)$ are all bounded below by $C \cdot \lambda^N$, which implies that there are “massive” coincidences, since $2^N - C \cdot \lambda^N$ spacings are zeros. This is an extreme case of attraction. Something similar happens for all zeros of $\{0, \pm 1\}$ polynomials.

On the other hand, consider the case of “Garsia numbers.” We say that θ is Garsia if it is a zero of a monic polynomial with integer coefficients and constant term ± 2 , whose conjugates are all greater than one in modulus. Garsia reciprocals include $2^{-1/k}$ for $k \geq 2$, but also many other numbers (e.g. the reciprocal of the positive root of $x^3 - 2x - 2 = 0$, which is about .5652, or the reciprocal of the positive root of $x^3 - x^2 - 2 = 0$, which is about .5898). Garsia reciprocals λ are the only *specific* (as opposed to generic) $\lambda \in (\frac{1}{2}, 1)$ for which it is known that ν_λ is absolutely continuous, and moreover, they have bounded density. Again by Garsia's Lemma [6], it is known that the spacings between points in $A_N(\lambda)$ are bounded below by $C \cdot 2^{-N}$, and there are no coincidences. This is an extreme case of repulsion.

It is interesting to compare our situation with that for sequences $\alpha n^d \bmod 1$, for irrational α and $d \geq 2$. It is conjectured that for α badly approximable by rationals the spacing distribution is Poissonian, and partial results in this direction are obtained in [16, 18], in particular, for a.e. α , the pair correlations converge to $2s$ as $N \rightarrow \infty$. On the other hand, [16, 18] show that for some irrational α the behavior of spacings is different. In our problem, we prove that for λ which are extremely well-approximable by zeros of $\{0, \pm 1\}$ polynomials, the pair correlation function $R_2(s, \lambda, 2^N)$ exhibits some attraction (Theorem 2.2).

There are several difficulties in pushing our results further; one of them is that the distribution of zeros of $\{0, \pm 1\}$ polynomials is not well-understood. In contrast with [18], we cannot say anything about higher-order correlations; this is related to hard open problems on Bernoulli convolutions. A technical assumption which we have to make in some results is that the parameter λ belongs to the “transversality interval,” that is, an interval where $\{0, \pm 1\}$ power series cannot have double zeros. Transversality [15, 20, 13, 14] has been crucially important in the work on ν_λ .

We note that there are some features of our sequences which are “non-random.” In particular, some spacings tend to have very high multiplicity, in other words, the distribution of non-rescaled spacings sometimes exhibit “spikes.” This is explained by the fact that every spacing g is a zero of a $\{0, \pm 1\}$ polynomial. For every such polynomial with k zero coefficients, the same difference between points in $A_N(\lambda)$ will be achieved 2^k times. If g is a very small number, it is likely to be a spacing, and if $N - k$ is small, we will see a “spike.” This irregularity should dissappear after rescaling by the CDF of ν_λ .

Further, it turns out that the smallest spacing between points of $A_N(\lambda)$, for a.e. λ in a transversality interval, is bounded below by $3^{-N}N^{-1-\varepsilon}$, for infinitely many N , for any $\varepsilon > 0$ (follows from Theorem 2.4), which is much larger than $(2^{-N})^2$ which we would get if the points were sampled randomly and independently from the uniform distribution.

In Figures 1-3 we show the histogram of the distribution of nearest-neighbor spacings and also spacings with $\ell = 2, 3$ for the rescaled points $\{\tilde{\xi}_{n,N}\}$, where $\lambda = 0.70880447$ was obtained from a random number generator, uniformly in the interval $[0.69, 0.71]$. It was chosen so as to be reasonably close to $2^{-1/2} = 0.7071\ldots$ for which the CDF of the infinite Bernoulli convolution measure is known precisely, and this CDF was used for the rescaling. The figures show reasonable agreement with the Poisson distribution (indicated by the curves). Note that the units on the horizontal axis are 2^{-N} . More details about the computations, *Mathematica* program, and additional simulations are collected in the Appendix at the end of the paper.

FIGURE 1. Nearest-neighbor spacings for rescaled points, $\lambda = 0.70880447$, $N = 22$.

FIGURE 2. Next-to-nearest-neighbor spacings for rescaled points, $\lambda = .70880447$, $N = 22$.

FIGURE 3. Spacings with $\ell = 3$ for rescaled points, $\lambda = .70880447$, $N = 22$.

2. RESULTS

Theorem 2.1. *Let $I = [\lambda_0, \lambda_1] \subset (\frac{1}{2}, 0.668)$. Then there exists C_1 (depending on I) such that*

$$(2.1) \quad \forall N \geq 1, \forall s > 0, \int_I R_2(s, \lambda, 2^N) d\lambda \leq C_1 s,$$

Remarks. 1. The appearance of the number 0.668 is due to “transversality;” it is explained in the next section. We do not know if the result holds all the way to 1, although numerical evidence indicates that things actually get better as λ increases.

2. By Fatou’s Lemma, we get $\int_I \liminf_{N \rightarrow \infty} R_2(s, \lambda, 2^N) d\lambda \leq C_1 s$ for $s > 0$. This shows that, on average, our spacing distributions exhibit no attraction, at least in the liminf sense. We note that in other problems, for instance, concerning the distribution of $\{n\alpha\}$ for irrational α , it is also common to average over the parameter, see [9, Th.3.2].

3. An application of Borel-Cantelli shows, for instance, that for any $\varepsilon > 0$, for a.e. $\lambda \in (\frac{1}{2}, 0.668)$,

$$(2.2) \quad \forall s > 0, R_2(s, \lambda, 2^N) \leq sN^{1+\varepsilon} \text{ for } N \text{ sufficiently large.}$$

4. An estimate analogous to (2.1) follows for the sets $A_N(\lambda) \cap J$, for an arbitrary fixed interval $J \subset [0, 1]$. Let $\#(J, N) = \#(A_N(\lambda) \cap J)$ and set

$$(2.3) \quad R_2(s, \lambda, J, N) := \frac{1}{\#(J, N)} \# \left\{ (x, y) : x \neq y, x, y \in A_N(\lambda) \cap J, |x - y| \leq \frac{s|J|}{\#(J, N)} \right\}.$$

Then, obviously,

$$R_2(s, \lambda, J, N) \leq R_2\left(\frac{s|J|}{\#(J, N)}, \lambda, 2^N\right) \frac{2^N}{\#(J, N)}.$$

Note that $\lim_{N \rightarrow \infty} \#(J, N)/2^N = \nu_\lambda(J) \in (0, 1)$, so we get an analog of (2.1) for $R_2(s, \lambda, J, N)$, with a constant $C_{1,J} \approx C_1|J|/\nu_\lambda(J)^2$ for large N .

5. If ν_λ has a density bounded below by $\eta > 0$ on an interval $J = [a, b] \subset [0, 1]$, then

$$\tilde{R}_2(s, \lambda, \tilde{J}, N) \leq R_2(s/\eta, \lambda, J, N),$$

where $\tilde{R}_2(s, \lambda, \tilde{J}, N)$ is the correlation sum analogous to (2.3) for the rescaled points $\tilde{\xi}_{n,N}$ in $\tilde{J} = [F_\lambda(a), F_\lambda(b)]$ (recall that F_λ is the CDF of ν_λ). It is known that the density ν_λ is bounded away from zero on $[\varepsilon, 1 - \varepsilon]$ for $\varepsilon > 0$, for a.e. $\lambda > 2^{-1/2}$, and numerical evidence suggests that this is true for a typical $\lambda > (\sqrt{5} - 1)/2 \approx .618$ as well.

The following theorem shows that (2.2) fails for many points.

Theorem 2.2. (i) *For any λ_0 which is a zero of a $\{0, \pm 1\}$ polynomial, there exists $\rho = \rho(\lambda_0) < 2$ such that*

$$(2.4) \quad |A_N(\lambda_0)| \leq C_2 \rho^N,$$

where $|A_N(\lambda_0)|$ is the size of the set without multiplicities. Thus,

$$(2.5) \quad R_2(0, \lambda_0, 2^N) \geq C_2^{-1} (2/\rho)^N - 1.$$

(ii) For any interval $I \subset (\frac{1}{2}, 1)$ and $\varepsilon > 0$, there is an uncountable set $\mathcal{E}_I \subset I$, such that for $\lambda \in \mathcal{E}_I$

$$(2.6) \quad \forall s > 0, \quad R_2(s, \lambda, 2^N) \geq 2^{N^{1-\varepsilon}} \quad \text{for infinitely many } N.$$

Remark. One can ask how large is the uncountable set $\mathcal{E}_I$ in terms of Hausdorff measure and dimension. Our proof certainly produces a set of Hausdorff dimension zero, but it shouldn't be hard to find a gauge function for which the Hausdorff measure is positive. We leave this to the interested reader.

Next we turn to the estimates from below.

Theorem 2.3. For any $\lambda_0 \in (\frac{1}{2}, 1)$, $\varepsilon \in (0, 1 - \lambda_0)$, and $L > 0$, there exists $C_3 = C_3(\lambda_0, \varepsilon) > 0$ such that

$$(2.7) \quad \forall N \geq 1, \quad \forall s \in (0, L), \quad \int_{\lambda_0 - \varepsilon}^{\lambda_0 + \varepsilon} R_2(s, \lambda, 2^N) d\lambda \geq C_3 s.$$

Remarks. 1. An analog of (2.7) holds for $R_2(s, \lambda, J, N)$, for any interval $J \subset [0, 1]$, with a constant $C_{3,J}$.

2. If ν_λ has a density bounded above by M , then the pair correlation for the rescaled points satisfies

$$\tilde{R}_2(s, \lambda, 2^N) \geq R_2(s/M, \lambda, 2^N).$$

It is known [20] that ν_λ has bounded density for a.e. $\lambda \in (2^{-1/2}, 1)$.

It is often more convenient (especially for the proofs) to work with

$$(2.8) \quad A'_N(\lambda) = \left\{ \sum_{n=0}^{N-1} a_n \lambda^n : a_n \in \{0, 1\} \right\} = (1 - \lambda)^{-1} A_N(\lambda)$$

and the corresponding correlation expression

$$R'_2(s, \lambda, 2^N) = \frac{1}{2^N} \# \left\{ (x, y) : x \neq y, x, y \in A'_N(\lambda), |x - y| \leq \frac{s}{2^N} \right\}.$$

Since $(1 - \lambda)^{-1}$ is uniformly bounded from zero and from infinity in all our theorems, proving results for $R'_2(s, \lambda, 2^N)$ will immediately imply the desired statements.

Next we consider the **smallest** and the **largest** gaps (spacings) for $A'_N(\lambda)$, which we denote $g_N(\lambda)$ and $G_N(\lambda)$ respectively. It is obvious that $g_N(\lambda) \leq (1 - \lambda)^{-1} 2^{-N}$. For Garsia reciprocals λ we have $g_N(\lambda) \geq c \cdot 2^{-N}$. It seems likely $g_N(\lambda) = o(2^{-N})$ for a typical λ , but we do not have a proof of this. The difficulty, again, is that we do not know much about the distribution of the zeros of $\{0, \pm 1\}$ -polynomials.

We have a lower bound for $g_N(\lambda)$ for a typical λ in the “transversality interval.”

Theorem 2.4. *Let $\alpha_N > 0$ be such that $\sum_N 3^N \alpha_N < \infty$. Then for Lebesgue a.e. $\lambda \in I = [\frac{1}{2}, 0.668]$ we have*

$$g_N(\lambda) > \alpha_N \text{ for infinitely many } N.$$

Concerning the largest gap, we do not have new results; we just note that questions related to $G_N(\lambda)$ have been studied by Erdős, Joó and Komornik (though they were couched in different terms). It is easy to see that $G_N(\lambda) \leq \lambda^{N-1}$ [4, Th.4(a)] (this follows by the “greedy algorithm”), and hence $G_N(\lambda) = \lambda^{N-1}$, since the ordered sequence $A'_N(\lambda)$ starts with $0, \lambda^{N-1}$. One can ask, however, whether this largest gap is realized away from the endpoints, as $N \rightarrow \infty$. The answer is “yes” for all $\lambda \in (\frac{1}{2}, \lambda_g)$, where $\lambda_g = (\sqrt{5} - 1)/2 \approx 0.618\dots$ is the golden ratio [4, Th.4(b)], in which case, for odd N ,

$$1 + \lambda^2 + \lambda^4 + \dots + \lambda^{N-3}, \quad 1 + \lambda^2 + \lambda^4 + \dots + \lambda^{N-3} + \lambda^{N-1}$$

are two consecutive points in $A'_N(\lambda)$. Erdős, Joó and Komornik [5, Th.5] also showed that $G_N(\lambda)$ is achieved at most K times, independent of N , and not at all in $(\varepsilon, (1 - \lambda)^{-1} - \varepsilon)$ for any $\varepsilon > 0$, for sufficiently large N , for all $\lambda \in (2^{-1/2}, 1)$ which are not zeros of $\{0, \pm 1\}$ polynomials. It is not known what happens between λ_g and $2^{-1/2}$, though it is reasonable to expect similar behavior (gaps of $o(\lambda^N)$, except near the endpoints), at least for typical λ .

3. PROOFS

We need a result about $\{0, \pm 1\}$ polynomials. Actually, it is convenient to state it for power series; of course this includes polynomials as a special case. Denote

$$\mathcal{B} = \left\{ 1 + \sum_{n=1}^{\infty} c_n x^n, \quad c_n \in \{-1, 0, 1\} \right\}.$$

Definition 3.1. *An interval $I \subset (0, 1)$ is called an interval of **transversality** for $\mathcal{B}$ if for every $f \in \mathcal{B}$, we have*

$$(3.1) \quad x \in I, \quad f(x) = 0 \Rightarrow f'(x) \neq 0.$$

Proposition 3.2. [19] *The interval $[\frac{1}{2}, 0.668]$ is an interval of transversality for $\mathcal{B}$.*

Transversality is used in the following lemma. The Lebesgue measure on the line will be denoted by $\mathcal{L}$.

Lemma 3.3. ([14, Lem. 4.2], *see also* [15]) *Let I be a closed interval of transversality for $\mathcal{B}$ and $g \in \mathcal{B}$. Then there exists $C > 0$, depending only on I , such that*

$$(3.2) \quad \forall \rho > 0, \quad \mathcal{L}\{\lambda \in I : |g(\lambda)| \leq \rho\} \leq C\rho.$$

Recall that we will be working with $A'_N(\lambda)$ and $R'_2(s, \lambda, 2^N)$, see (2.8).

Proof of Theorem 2.1. Our proof mimics the argument in [13], but we have to work with finite sums instead of power series. Let $\Omega_N = \{0, 1\}^N$ and $\pi_\lambda^N(\omega) = \sum_{n=0}^{N-1} \omega_n \lambda^n$ for $\omega = \omega_0 \dots \omega_{N-1} \in \Omega_N$. Note that $A'_N(\lambda) = \pi_\lambda^N(\Omega_N)$. We will assume that π_λ is 1-to-1 on Ω_N , in other words, λ is not a zero of a $\{0, \pm 1\}$ polynomial, which only excludes a countable set from I . Further, let μ_N be the uniform (counting) measure on Ω_N , with each point having equal weight 2^{-N} . We have, by definition,

$$R'_2(s, \lambda, N) = 2^N (\mu_N \times \mu_N) \{(\omega, \tau) \in \Omega_N^2 : \omega \neq \tau, |\pi_\lambda^N(\omega) - \pi_\lambda^N(\tau)| \leq s 2^{-N}\}.$$

By Fubini's Theorem,

$$(3.3) \quad \int_I R'_2(s, \lambda, N) d\lambda = 2^N \iint_{\Omega_N^2 \setminus \text{Diag}} \mathcal{L}\{\lambda \in I : |\pi_\lambda^N(\omega) - \pi_\lambda^N(\tau)| \leq s 2^{-N}\} d\mu_N(\omega) d\mu_N(\tau),$$

where $\text{Diag} = \{(\omega, \omega) : \omega \in \Omega\}$. We have

$$(3.4) \quad \pi_\lambda^N(\omega) - \pi_\lambda^N(\tau) = \sum_{n=0}^{N-1} (\omega_n - \tau_n) \lambda^n = \pm \lambda^k g(\lambda),$$

where $k = |\omega \wedge \tau| = \min\{n : \omega_n \neq \tau_n\} \leq N-1$, and g is a $\{0, \pm 1\}$ polynomial with constant term 1, hence $g \in \mathcal{B}$. By (3.4), $|\pi_\lambda^N(\omega) - \pi_\lambda^N(\tau)| \leq s 2^{-N}$ implies $|g(\lambda)| \leq \lambda_0^{-k} s 2^{-N} =: \rho$ for $\lambda \in I = [\lambda_0, \lambda_1]$. Applying (3.2) yields

$$\mathcal{L}\{\lambda \in I : |\pi_\lambda^N(\omega) - \pi_\lambda^N(\tau)| \leq s 2^{-N}\} \leq C \lambda_0^{-k} s 2^{-N},$$

and we obtain from (3.3):

$$\begin{aligned} \int_I R'_2(s, \lambda, N) d\lambda &\leq C s \iint_{\Omega_N^2 \setminus \text{Diag}} \lambda_0^{-|\omega \wedge \tau|} d\mu_N(\omega) d\mu_N(\tau) \\ &= C s \sum_{k=0}^{N-1} \lambda_0^{-k} (\mu_N \times \mu_N) \{(\omega, \tau) : |\omega \wedge \tau| = k\} \\ &= C s \sum_{k=0}^{N-1} \lambda_0^{-k} 2^{-k-1} < \frac{C \lambda_0 \cdot s}{2 \lambda_0 - 1}, \end{aligned}$$

proving (2.1). □

Proof of Theorem 2.2. (i) Let λ_0 be a zero of a $\{0, \pm 1\}$ polynomial, that is,

$$1 + \sum_{n=1}^k c_n \lambda^n = 0, \quad \text{with } c_n \in \{0, \pm 1\}.$$

We can write $c_n = u_n - v_n$ for some $u_n, v_n \in \{0, 1\}$, $n = 1, \dots, k$. It follows that $1 + \sum_{n=1}^k u_n \lambda^n = \sum_{n=1}^k v_n \lambda^n$, which means that every occurrence (not just at the beginning) of the “block” $(1u_1 \dots u_k)$ in a sequence $a_0 \dots a_{N-1}$ representing a point in $A'_N(\lambda_0)$, can be replaced by $(0u_1 \dots u_k)$, without changing the value of the sum, in other words, yielding the same point in $A'_N(\lambda_0)$. It follows that $|A'_N(\lambda_0)|$ is bounded above by the number of “words” of length N in the shift of finite type consisting of all 0, 1 sequences which do not contain the “forbidden” block $(1u_1 \dots u_k)$, see [8, Ch.2]. Further, it is known (see [8]) that the number of words of length N in a shift of finite type is not greater than $\text{const} \cdot \rho^N$, where ρ is the topological entropy. The entropy of the full shift on two symbols is 2, and every “forbidden word” results in a drop of entropy, see [8, Th.4.4.7]. Thus, $\rho < 2$, and (2.4) is proved. Now (2.5) follows from the Cauchy-Schwartz inequality: the 2^N points of $A_N(\lambda)$ (counted with multiplicity) are grouped into at most $\text{const} \cdot \rho^N$ distinct values, and the sum of the squares of multiplicities is equal to $2^N(R_2(0, \lambda_0, 2^N) + 1)$ (the “+1” comes from the diagonal).

(ii) Let $\mathcal{Z}$ denote the set of zeros of $\{0, \pm 1\}$ polynomials. Observe that $\mathcal{Z}$ is dense in $(\frac{1}{2}, 1)$. Indeed, given $\lambda \in (\frac{1}{2}, 1)$, for any k , we can find $c_1 = 1, c_2, \dots, c_k \in \{0, 1\}$ such that $1 - \sum_{n=1}^k c_n \lambda^n \in [0, \lambda^k)$ (e.g. by the “greedy” algorithm). Then $p(x) = 1 - \sum_{n=1}^k c_n x^n$ has derivative $p'(x) \leq -1$ and hence p has a zero in $[\lambda, \lambda + \lambda^k)$.

We construct points $\lambda \in I$, extremely well approximable by points in $\mathcal{Z}$, to ensure that (2.6) holds. We do this inductively. First find $\lambda_0 \in \mathcal{Z} \cap I$ and find N_0 so large that $R_2(0, \lambda_0, 2^{N_0}) \geq 2^{N_0^{1-\varepsilon}}$, which is possible by (2.4). Then we find a closed interval I_1 around λ_0 , so small that

$$R_2(1, \lambda, 2^{N_0}) \geq 2^{N_0^{1-\varepsilon}} \quad \text{for } \lambda \in I_1,$$

which is possible by continuity. We continue this process and find closed intervals $I \supset I_1 \supset \dots \supset I_k \supset \dots$ and positive integers $N_0 < N_1 < \dots < N_k < \dots$, so that

$$R_2(2^{-k}, \lambda, 2^{N_k}) \geq 2^{N_k^{1-\varepsilon}} \quad \text{for } \lambda \in I_k, \quad k \geq 1.$$

We are using density of $\mathcal{Z}$ and (2.4) at each step (however, the exponential rate depends on the point in $\mathcal{Z}$, so $N_{k+1} - N_k$ may be quite large). Clearly $\lambda \in \bigcap_{k=1}^{\infty} I_k$ will satisfy (2.6). Modifying the construction slightly, namely, choosing two distinct points in $\mathcal{Z}$ in

an interval and two disjoint intervals around them at each stage, we obtain a Cantor set of points in I for which (2.6) holds. $\square$

Proof of Theorem 2.3. The claim (2.7) will follow if we prove that

$$(3.5) \quad \mathcal{I}(s) := \int_{\lambda_0 - \varepsilon}^{\lambda_0 + \varepsilon} R'_2(s, \lambda, 2^N) d\lambda \geq C'_3 s.$$

For any $k \geq 1$ we can find $c_1 = 1, c_2, \dots, c_k \in \{0, 1\}$ by the greedy algorithm, so that

$$1 - \sum_{n=1}^k c_n \lambda_0^n \in [0, \lambda_0^k).$$

Choose k so that $\lambda_0^k < \varepsilon/10$. We have $k \geq 4$, since $\lambda_0 > \frac{1}{2}$. The idea is that for some integer ℓ , for N sufficiently large, the pair of points $x(\lambda), y(\lambda) \in A'_N(\lambda)$, where

$$x(\lambda) = 1 + \sum_{n=k+\ell+1}^{N-1} a_n \lambda^n, \quad y(\lambda) = \sum_{n=1}^k c_n \lambda^n + \sum_{n=k+\ell+1}^{N-1} b_n \lambda^n,$$

will satisfy $|x(\lambda) - y(\lambda)| < s/2^N$ for all λ in an interval of size $\geq \text{const} \cdot s/2^N$ contained in $(\lambda_0 - \varepsilon, \lambda_0 + \varepsilon)$, for all choices of $a_n, b_n \in \{0, 1\}$. This will contribute $\geq \text{const} \cdot (s/2^N) \cdot (4^{N-k-\ell-1}/2^N) = \text{const} \cdot s$ to the integral in (3.5), proving the estimate. Now for the details. Consider

$$(3.6) \quad f(\lambda) := x(\lambda) - y(\lambda) = 1 - c_1 \lambda - c_2 \lambda^2 - \dots - c_k \lambda^k + \sum_{n=k+\ell+1}^{N-1} (a_n - b_n) \lambda^n.$$

We have

$$|f(\lambda_0)| < \lambda_0^k + \frac{\lambda_0^{k+\ell+1}}{1 - \lambda_0} < \frac{\varepsilon}{10} + \frac{\varepsilon}{10} \frac{\lambda_0^{\ell+1}}{(1 - \lambda_0)}.$$

Assume that ℓ satisfies

$$(1 - \lambda_0)^{-1} \lambda_0^{\ell+1} < 1$$

(there will be another condition on ℓ below). Then

$$(3.7) \quad |f(\lambda_0)| < \frac{\varepsilon}{5}.$$

Now we need to estimate $f'(\lambda)$ for $\lambda \in (\lambda_0 - \varepsilon, \lambda_0 + \varepsilon)$. We have

$$(3.8) \quad |f'(\lambda)| \leq \sum_{n=1}^{\infty} n \lambda^{n-1} = (1 - \lambda)^{-2}.$$

On the other hand, since $c_1 = 1$ and $c_n \geq 0$, we obtain from (3.6):

$$f'(\lambda) \leq -1 + \sum_{n=k+\ell+1}^N n \lambda^{n-1} \leq -1 + \frac{k + \ell + 2}{(1 - \lambda)^2} \lambda^{k+\ell}.$$

Let $\lambda_1 = \lambda_0 + \varepsilon$ and assume that $\ell \in \mathbb{N}$ is such that

$$\frac{k + \ell + 2}{(1 - \lambda_1)^2} \lambda_1^{k+\ell} \leq \frac{1}{2},$$

then

$$(3.9) \quad f'(\lambda) \leq -1/2 \quad \text{for all } \lambda \in (\lambda_0 - \varepsilon, \lambda_0 + \varepsilon).$$

From (3.7) and (3.9) it follows that there exists $\gamma \in [\lambda_0 - \frac{2\varepsilon}{5}, \lambda_0 + \frac{2\varepsilon}{5}]$ such that $f(\gamma) = 0$. Then (3.8) implies that

$$|f(\lambda)| < s2^{-N} \quad \text{for } \lambda \in (\gamma - (1 - \lambda_1)^2 s2^{-N}, \gamma + (1 - \lambda_1)^2 s2^{-N}),$$

and we have $s2^{-N}(1 - \lambda_1)^2 < \frac{3\varepsilon}{5}$ for large N . Thus, any choice of $a_n, b_n \in \{0, 1\}$, with $n \in [k + \ell + 1, N - 1] \cap \mathbb{N}$, contributes at least $s2^{-N}(1 - \lambda_1)^2 \cdot 2^{-N}$ to the integral $\mathcal{I}(s)$, and taking all the $4^{N-k-\ell-1}$ choices into account yields (2.7). $\square$

Proof of Theorem 2.4. It is clear that $g_N(\lambda) = \sum_{n=0}^{N-1} (a_n - b_n) \lambda^n$ for some $a_n, b_n \in \{0, 1\}$, hence $g_N(\lambda) = \lambda^k |p_{N-k}(\lambda)|$ for some polynomial $p_{N-k} \in \mathcal{B}$ of degree $N - k - 1$, where $k \in \{0, 1, \dots, N - 2\}$. If $g_N(\lambda) \leq \alpha_N$, then

$$0 \leq |p_{N-k}(\lambda)| \leq \alpha_N \lambda^{-k} \leq \alpha_N 2^k.$$

By Lemma 3.3,

$$\mathcal{L}\{\lambda \in I : |p_{N-k}(\lambda)| \leq \alpha_N 2^k\} \leq C \alpha_N 2^k.$$

There are 3^{N-k-1} polynomials of degree $N - k - 1$ in $\mathcal{B}$. Let

$$E_N = \left\{ \lambda \in I : g_N(\lambda) \leq \alpha_N \right\}.$$

It follows that

$$\mathcal{L}(E_N) \leq C \alpha_N \sum_{k=0}^{N-1} 2^k \cdot 3^{N-k-1} < C \alpha_N 3^N.$$

Recalling that $\sum_N \alpha_N 3^N < \infty$ we conclude by Borel-Cantelli that a.e. $\lambda \in I$ does not belong to E_N for infinitely many N , proving the claim. $\square$

4. APPENDIX: NUMERICAL EXPERIMENTS

In Figure 4 we show the histograms for the non-rescaled and rescaled data sets for $\lambda = 0.6429$, which was chosen randomly. For all rescalings we used the density for the parameter $2^{-1/2}$ given by

$$F(x) = \begin{cases} ax^2/2, & x \in [0, b] \\ ab(x-b), & x \in [b, 1-b] \\ 1-a(1-x)^2/2, & x \in [1-b, 1] \end{cases}, \text{ where } a = 1.5\sqrt{2} + 2, \ b = \sqrt{2} - 1.$$

This “improved” the distribution of spacings even for λ not very close to $2^{-1/2}$. In the histogram, we used the 50 “bins” from $0.1 \cdot 2^{-N}$ to $5 \cdot 2^N$.

FIGURE 4. Spacings for a “random” $\lambda = .6429$, $N = 22$.

Similar results (though, admittedly, some showing less accurate fit) were obtained for more than 20 values of λ in the range $[0.62, 0.78]$. For some values we went up to $N = 25$, but this significantly increased the computing time without noticeable advantage.

We also tried λ close to a Pisot reciprocal and to Garsia reciprocal. In Figure 5 we took $\lambda = 0.6518$ which is close to the Pisot reciprocal $0.651822\dots$; we still see “exponential-like” distribution, but there is definite “attraction” visible. For $\lambda = 0.652$ this effect was no longer felt. In Figure 6 we took $\lambda = 0.70710678$ which is within about 10^{-9} to $2^{-1/2}$, a Garsia reciprocal. It shows a very dramatic “repulsion.” This effect was not felt for $\lambda = 0.7071$.

FIGURE 5. Near Pisot: $\lambda = .6518$, $N = 22$.FIGURE 6. Near Garsia: $\lambda = .70710678$, $N = 22$.

To conclude, we provide the *Mathematica 6.0* program used to create these figures. We use $\lambda = \text{lam} = 0.6429$, $N = 22$; $\ell = \text{ell} = 1$ means that we consider nearest-neighbor spacings. We then just change these parameters. **Spac** and **SpacR** produce the histograms of spacings for non-rescaled and rescaled points, respectively.

```
Needs["Histograms`"]
a = 1.5*Sqrt[2.] + 2.; b = Sqrt[2.] - 1.
F[x_] := Which[x < b, a*x^2/2., x > 1 - b,
1 - a (1 - x)^2/2., True, a*b^2/2 + a*b*(x - b)]
lam = 0.6429; N= 22; ell=1; Clear[g]; g[A_] := Union[lam A, lam A + 1]
Tru = Nest[g, {0}, N] (1 - lam);
Vru = Drop[RotateLeft[Pru,ell] - Pru, -ell] 2^N;
Spac = Histogram[Vru, HistogramRange -> {0, 5*ell},
HistogramCategories -> 50, ApproximateIntervals -> False]
Pru = Table[F[Tru[[i]]], {i, 1, 2^N}];
Vuru = Drop[RotateLeft[Pru,ell] - Pru, -1] 2^N;
SpacR = Histogram[Vuru, HistogramRange -> {0, 5*ell},
HistogramCategories -> 50, ApproximateIntervals -> False]
```

We compared the histograms with appropriately rescaled Poisson distribution as follows:

```
Pois[s_,ell_,N_] := .1*ell*2^N*s^(ell-1) Exp[-s]/(ell-1)!
Plot[Pois[s,ell,n], {s, 0, 5*ell}, PlotRange -> All]
```

Acknowledgment. We are grateful to Rick Kenyon for his ideas at the initial stage of this work. Thanks also to Yury Makarychev for some help with simulations.
